

CSG1102 – Workshop 7 RAID 5

Introduction

A very basic parity implementation has been performed for redundancy purposes on some ASCII encoded text. A two stage XOR process has been used in order to simulate RAID 5 redundancy. This process is outlined below

In this example we have three inputs the characters 'A', 'B' and 'C'. We have first gotten the result of 'A' XOR 'B' and then used the output as an input for XOR 'C'. Through this we have a parity value to store for redundancy purposes. If any one of the values 'A', 'B', or 'C' are lost we are able to reconstruct the value through a series of XOR operations

Your Task

Your task is to reconstruct a short message, which has been subject to data loss. In this example an X indicates corrupted data where a 0 or 1 should be. In reality however corrupted data is normally determined through the use of a checksum or other mechanism.

| BYTE 1 | BYTE 2 | BYTE 3 | PARITY BYTE |
|----------|----------|----------|-------------|
| 01000111 | 01101111 | 011011XX | 01000111 |
| 01X00100 | 00100000 | 01101110 | 00101010 |
| 01100101 | 01110111 | 011XXX11 | 01100001 |
| 00XXX000 | 01100101 | 01110110 | 00110011 |
| 01100101 | 01110010 | 01111001 | 01101110 |
| 01100010 | 011X1111 | 01100100 | 01101001 |
| 01111001 | 0X100000 | 0010XX00 | 01111001 |
